1. What does a neuron compute?

A neuron computes a function g that scales the input x linearly (Wx + b)

A neuron computes an activation function followed by a linear function (z = Wx + b)

A neuron computes a linear function (z = Wx + b) followed by an activation function

Correct

Correct, we generally say that the output of a neuron is a = g(Wx + b) where g is the activation function (sigmoid, tanh, ReLU, ...).

2. Which of these is the "Logistic Loss"?

$$igcup_{i} \mathcal{L}^{(i)}(\hat{y}^{(i)},y^{(i)}) = \mid y^{(i)} - \hat{y}^{(i)}\mid^2$$

Correct

Correct, this is the logistic loss you've seen in lecture!

$$igcup \mathcal{L}^{(i)}(\hat{y}^{(i)},y^{(i)}) = \mid y^{(i)} - \hat{y}^{(i)} \mid i$$

$$\mathcal{L}^{(i)}(\hat{y}^{(i)},y^{(i)}) = max(0,y^{(i)}-\hat{y}^{(i)})$$

3. Suppose img is a (32,32,3) array, representing a 32x32 image with 3 color channels red, green and blue. How do you reshape this into a column vector?

x = img.reshape((1,32*32,*3))

x = img.reshape((3,32*32))

x = img.reshape((32*32*3,1))

Correct

4. Consider the two following random arrays "a" and "b":

```
1 a = np.random.randn(2, 3) # a.shape = (2, 3)
2 b = np.random.randn(2, 1) # b.shape = (2, 1)
3 c = a + b
```

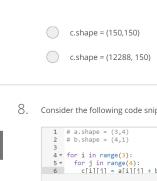

What will be the shape of "c"?

c.shape = (2, 3)

Yes! This is broadcasting. b (column vector) is copied 3 times so that it can be summed to each column of a. c.shape = (3, 2)The computation cannot happen because the sizes don't match. It's going to be "Error"! c.shape = (2, 1) Consider the two following random arrays "a" and "b": 1 a = np.random.randn(4, 3) # a.shape = (4, 3)
2 b = np.random.randn(3, 2) # b.shape = (3, 2)
3 c = a*b What will be the shape of "c"? c.shape = (4,2) The computation cannot happen because the sizes don't match. It's going to be "Error"! Correct Indeed! In numpy the "*" operator indicates element-wise multiplication. It is different from "np.dot()". If you would try "c = np.dot(a,b)" you would get c.shape = (4, 2). c.shape = (4, 3) c.shape = (3, 3) Suppose you have n_x input features per example. Recall that $X = [x^{(1)}x^{(2)}...x^{(m)}]$. What is the dimension of X? (n_x, m) Correct $\bigcirc \qquad (1,m)$ (m, n_x) (m, 1)7. Recall that "np.dot(a,b)" performs a matrix multiplication on a and b, whereas "a*b" performs an element-wise multiplication. Consider the two following random arrays "a" and "b": 1 a = np.random.randn(12288, 150) # a.shape = (12288, 150)
2 b = np.random.randn(150, 45) # b.shape = (150, 45)
3 c = np.dot(a,b) What is the shape of c? The computation cannot happen because the sizes don't match. It's going to be "Error"! c.shape = (12288, 45) Correct, remember that a np.dot(a, b) has shape (number of rows of a, number of columns of b). The sizes match because: "number of columns of a = 150 = number of rows of b"

Trumber of columns of a = 150 = framber of rows of t

Consider the following code snippet:

```
2 # 0.500p.
3
4 * for i in range(3):
5 * for j in range(4):
6 c[i][i] = a[i][i] + b[i]
```

How do you vectorize this?

```
c = a.T + b.T
    c = a.T + b
    c = a + b
    c = a + b.T
```

Correct

9. Consider the following code:

```
1 a = np.random.randn(3, 3)
2 b = np.random.randn(3, 1)
3 c = a*b
```

What will be c? (If you're not sure, feel free to run this in python to find out).

This will invoke broadcasting, so b is copied three times to become (3,3), and \ast is an element-wise product so c.shape will be (3, 3)

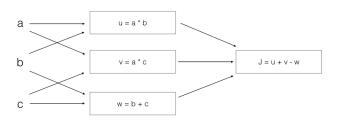

Correct

- This will invoke broadcasting, so b is copied three times to become (3, 3), and \ast invokes a matrix multiplication operation of two 3x3 matrices so c.shape will be
- This will multiply a 3x3 matrix a with a 3x1 vector, thus resulting in a 3x1 vector. That is, c.shape = (3,1).
- It will lead to an error since you cannot use "*" to operate on these two matrices. You need to instead use np.dot(a,b)

10. Consider the following computation graph.

What is the output J?

orrect

Yes. J = u + v - w = a*b + a*c - (b + c) = a*(b + c) - (b + c) = (a - 1)*(b + c).

 $\int a^*b + b^*c + a^*c$

J = (b - 1) * (c + a)
